## MATH3821 Assignment 1

Kevin Li, Kevin Lou, Stephen Sung, Brandon Wong, Jason Zhu

## Question 1

For Simple Linear Regression model  $y_i = \beta_0 + \beta_1 x_i + \epsilon_i$  where  $\epsilon_i \sim N(0, \sigma^2)$ .

- a) Let  $\beta_0 = \alpha \beta_1 \bar{x}$ . Then the SLR model can be expressed as  $y_i = \alpha + \beta_1 (x_i \bar{x}) + \epsilon_i$ .
- b)  $\alpha$  equivalent to the mean response  $(\alpha = \beta_0 + \beta_1 \bar{x})$  of the previous SLR model and is the intercept of the new model
- c) To find the closed form formula of the LSE,

$$RSS(\beta_1) = \sum_{i=1}^{n} [y_i - (\alpha + \beta_1(x_i - \bar{x}))]^2$$

$$\frac{\partial RSS(\beta_1)}{\partial \alpha} = -2 \sum_{i=1}^{n} (y_i - (\alpha + \beta_1(x_i - \bar{x})))$$

$$\frac{\partial RSS(\beta_1)}{\partial \beta_1} = -2 \sum_{i=1}^{n} (y_i - (\alpha + \beta_1(x_i - \bar{x})))(x_i - \bar{x}))$$
(2)

Let Equation (1) = 0

$$-2\sum_{i=1}^{n} (y_i - (\hat{\alpha} + \hat{\beta}_1(x_i - \bar{x}))) = 0$$

$$\sum_{i=1}^{n} y_i - \sum_{i=1}^{n} \hat{\alpha} - \sum_{i=1}^{n} \hat{\beta}_1 x_i + \sum_{i=1}^{n} \hat{\beta}_1 \bar{x} = 0$$

$$n\hat{\alpha} = \sum_{i=1}^{n} y_i - \hat{\beta}_1 \sum_{i=1}^{n} x_i + n\hat{\beta}_1 \bar{x}$$

$$\hat{\alpha} = \frac{1}{n} \sum_{i=1}^{n} y_i - \hat{\beta}_1 \bar{x} + \hat{\beta}_1 \bar{x}$$

$$\hat{\alpha} = \bar{y}$$

Let Equation (2) = 0

$$-2\sum_{i=1}^{n} \left( y_i - (\hat{\alpha} + \hat{\beta}_1(x_i - \bar{x})))(x_i - \bar{x}) \right) = 0$$

$$\sum_{i=1}^{n} y_i(x_i - \bar{x}) - \sum_{i=1}^{n} \hat{\alpha}(x_i - \bar{x}) - \sum_{i=1}^{n} \hat{\beta}_1(x_i - \bar{x})^2 = 0$$

$$\hat{\beta}_1 \sum_{i=1}^{n} (x_i - \bar{x})^2 = \sum_{i=1}^{n} (y_i - \hat{\alpha})(x_i - \bar{x})$$

since  $\hat{\alpha} = \bar{y}$ 

$$\hat{\beta}_1 = \frac{\sum_{i=1}^n (y_i - \bar{y})(x_i - \bar{x})}{\sum_{i=1}^n (x_i - \bar{x})^2}$$

d)

$$Var[\hat{\alpha}] = Var \left[ \frac{1}{n} \sum_{i=1}^{n} y_i \right]$$
$$= \frac{1}{n^2} Var \left[ \sum_{i=1}^{n} y_i \right]$$

Since all  $y_i$ 's are uncorrelated

$$= \frac{1}{n^2} \sum_{i=1}^n Var[y_i]$$

$$= \frac{1}{n^2} \sum_{i=1}^n \sigma^2$$

$$= \frac{n\sigma^2}{n^2}$$

$$= \frac{\sigma^2}{n}$$

Therefore  $Var[\hat{\alpha}] = \frac{\sigma^2}{n}$ .

We note that  $\sum_{i=1}^{n} (y_i - \bar{y})(x_i - \bar{x}) = \sum_{i=1}^{n} (x_i - \bar{x})y_i$ , since

$$\sum_{i=1}^{n} (y_i - \bar{y})(x_i - \bar{x}) = \sum_{i=1}^{n} y_i(x_i - \bar{x}) - \sum_{i=1}^{n} \bar{y}(x_i - \bar{x})$$

and we notice that

$$\sum_{i=1}^{n} (x_i - \bar{x}) = \sum_{i=1}^{n} x_i - \frac{1}{n} n \sum_{i=1}^{n} x_i = 0$$

To calculate  $Var[\hat{\beta_1}]$ ,

$$Var[\hat{\beta}_{1}] = Var\left[\frac{\sum_{i=1}^{n}(x_{i}-\bar{x})y_{i}}{\sum_{i=1}^{n}(x_{i}-\bar{x})^{2}}\right]$$
$$= \frac{1}{\left(\sum_{i=1}^{n}(x_{i}-\bar{x})^{2}\right)^{2}}Var\left[\sum_{i=1}^{n}(x_{i}-\bar{x})y_{i}\right]$$

Since all  $y_i$  are independent

$$= \frac{1}{\left(\sum_{i=1}^{n} (x_i - \bar{x})^2\right)^2} \sum_{i=1}^{n} Var \left[ (x_i - \bar{x})y_i \right]$$

$$= \frac{1}{\left(\sum_{i=1}^{n} (x_i - \bar{x})^2\right)^2} \sum_{i=1}^{n} (x_i - \bar{x})^2 Var \left[ y_i \right]$$

$$= \frac{1}{\left(\sum_{i=1}^{n} (x_i - \bar{x})^2\right)^2} \sum_{i=1}^{n} (x_i - \bar{x})^2 \sigma^2$$

$$= \frac{\sigma^2}{\sum_{i=1}^{n} (x_i - \bar{x})^2}$$

Let  $S_{xx} = \sum_{i=1}^{n} (x_i - \bar{x})^2$  and  $S_{xy} = \sum_{i=1}^{n} (x_i - \bar{x})y_i$ . To calculate  $Cov[\hat{\alpha}, \hat{\beta_1}]$ 

$$\begin{split} Cov[\hat{\alpha}, \hat{\beta_1}] &= Cov[\bar{y}, \hat{\beta_1}] \\ &= Cov\left[\bar{y}, \frac{S_{xy}}{S_{xx}}\right] \\ &= \frac{1}{S_{xx}}Cov\left[\bar{y}, S_{xy}\right] \\ &= \frac{1}{S_{xx}}Cov\left[\frac{1}{n}\sum_{i=1}^n y_i, S_{xy}\right] \\ &= \frac{1}{nS_{xx}}Cov\left[\sum_{i=1}^n y_i, \sum_{j=1}^n (x_j - \bar{x})y_j\right] \\ &= \frac{1}{nS_{xx}}\sum_{i=1}^n \sum_{j=1}^n (x_j - \bar{x})Cov[y_i, y_j] \end{split}$$

When  $i \neq j$ ,  $Cov[y_i, y_j] = 0$  since all  $y_i$  are uncorrelated with each other, and  $Cov[y_i, y_j] = Var[y_i]$  when i = j

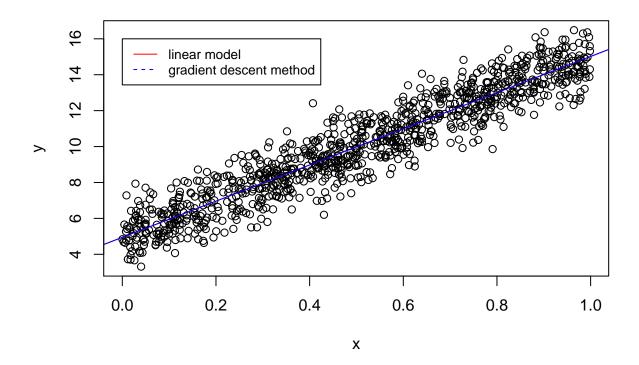

$$= \frac{1}{nS_{xx}} \sum_{i=1}^{n} (x_i - \bar{x})\sigma^2$$
$$= 0$$

```

#We can see that values are the same
#1 iterations was required
#It took alot less iterations than the gradient descent method
#This could be due to the fact that the Newton-raphson method
#accounts for the curvature of the loglikelihood and as such should need less iterations
#Below is the working to find the hessian matrix for the RSS

To get the Hessian matrix of the RSS we need to further derive the gradient found in Question 1e with respect to  $\alpha$  and  $\beta_1$ .

$$S'(\alpha, \beta_1) = \left(-2\sum_{i=1}^n (y_i - \alpha - \beta_1(x_i - \bar{x})), -2\sum_{i=1}^n (x_i - \bar{x})(y_i - \alpha - \beta_1(x_i - \bar{x}))\right)$$

$$\frac{\partial^2 S(\alpha, \beta_1)}{\partial \alpha^2} = 2\sum_{i=1}^n 1$$

$$= 2n$$

$$\frac{\partial^2 S(\alpha, \beta_1)}{\partial \beta_1^2} = 2\sum_{i=1}^n (x_i - \bar{x})(x_i - \bar{x})$$

$$= 2\sum_{i=1}^n (x_i - \bar{x})^2$$

$$\frac{\partial^2 S(\alpha, \beta_1)}{\partial \alpha \partial \beta_1} = 2\sum_{i=1}^n (x_i - \bar{x})$$

$$= \frac{\partial^2 S(\alpha, \beta_1)}{\partial \beta_1 \partial \alpha}$$

## Question 2

Given n independent binary random variables  $Y_1 \cdots Y_n$  with

$$P(Y_i = 1) = \pi_i \text{ and } P(Y_i = 0) = 1 - \pi_i$$

The probability function of  $Y_i$  is:

$$\pi_i^{Y_i} (1 - \pi_i)^{1 - Y_i}$$

where  $Y_i = 0$  or 1

a) For a probability function to belong to the exponential family of distributions, it must follow the formula:

$$f(y; \theta, \phi) = K(y, \frac{p}{\phi}) \exp\left(\frac{p}{\phi} \{y\theta - c(\theta)\}\right)$$

For the given probability density function:

$$f(y; \pi) = \pi^{y} (1 - \pi)^{1-y}$$

$$= \exp \left(\log \pi^{y} (1 - \pi)^{1-y}\right)$$

$$= \exp \left(\log \pi^{y} + \log(1 - \pi)^{1-y}\right)$$

$$= \exp \left(y \log \pi + (1 - y) \log(1 - \pi)\right)$$

$$= \exp \left(y \log(\frac{\pi}{1 - \pi}) + \log(1 - \pi)\right)$$

With p=1 and  $\phi=1$ , the above equation follows the form of the exponential family of distribution where  $K(y,\frac{p}{\phi})=1,\ \theta=\log(\frac{\pi}{1-\pi})$  and  $c(\theta)=-\log(1-\pi)=-\log(1-\frac{e^{\theta}}{1+e^{\theta}})$  where  $\pi=\frac{e^{\theta}}{1+e^{\theta}}$ .

- b) As seen in 2a, the naturalised parameter is  $\theta = \log(\frac{\pi}{1-\pi})$
- c) As seen in 2a, the cumulant generator is  $c(\theta) = -\log(1 \frac{e^{\theta}}{1 + e^{\theta}})$ . Since  $E[Y] = c'(\theta)$ ,  $c'(\theta) = -(\frac{e^{\theta}}{1 + e^{\theta}}) = -(-\pi) = \pi$ . Therefore,  $E[Y] = \pi$ .
- d) Given the link function:

$$g(\pi) = \log(\frac{\pi}{1 - \pi}) = e^{x^T \beta}$$

it can be rearranged in terms of the probability  $\pi$ ,

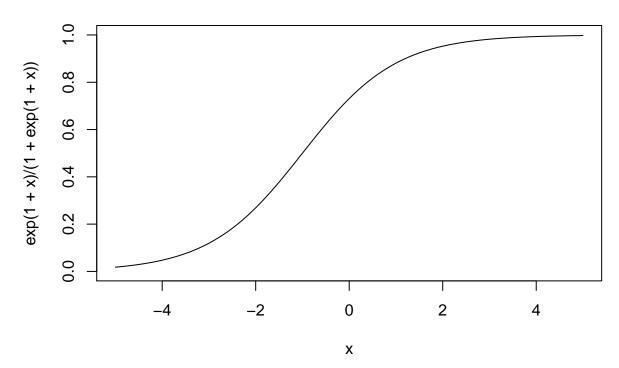

$$e^{x^T\beta} = \log(\frac{\pi}{1-\pi})$$

$$e^{x^T\beta} - \pi e^{x^T\beta} = \pi$$

$$\pi = \frac{e^{x^T\beta}}{1+e^{x^T\beta}}$$

e)

Graph of 
$$\log(\pi/1-\pi)=x^T\beta=\beta_1+\beta_2x$$

It shows the log odds of the insecticide working with a given probability, with increasing dosage increasing the probability of insecticide working.

f) The following probability density function:

$$f(y;\theta) = \frac{1}{\phi} \exp\left(\frac{(y-\theta)}{\phi} - \exp\left[\frac{(y-\theta)}{\phi}\right]\right)$$

is NOT in the exponential family of distributions as it does not follow the form of a probability density function in the exponential family. There is not a way to rearrange the probability density function such that it follows the form of a function in the exponential family, given in 2a, as isolating y from the inner exponential function is not possible and there is no  $\theta$  component/naturalised parameter.
